

# Design Methods

The design methods described in this diagram are used and taught at the Institute of Design for projects in design planning as well as for the design of products, services, and communications.

Horizontal bands indicate the level of focus that a design project takes. They correspond roughly to the nature of the design problem that the project addresses. Early research and objectives for design planning projects tend to target the high levels of the industry or organization in addressing *problems of competitive response, while*

*problems of user productivity, performance, understanding, or satisfaction* more often call for research focused on particular user activity domains. Rigorous investigations of any design problem will expand and contract through all levels of focus.

These human-centered design research methods may also be applied to common problems of application – which begin with some element of a design solution: a technology or material, a target market segment, or an existing product in need of simple enhancement.

Design methods are here mapped onto a schematic representation of the iterative process of design. The four phases or modes are artificial partitions of a complex and simultaneous activity. They describe a process of design in terms of the basic, human cognitive ability to move fluidly back and forth between the abstract or conceptual, and the real, physical world of activities, objects and signs. In addition, they distinguish between analytic modes of describing and understanding a problem space, and synthetic phases in which new solutions, new forms, and new realities are conceived and implemented.

Not all methods fall cleanly into one or another phase of the process. Some formalized design methods span all four operational phases and are more properly described as processes or procedures.

industry  
or arena

secondary research / literature search  
review of secondary source materials including pertinent written and pictorial information; useful in grounding observations and forming an historical basis for trend projections.

company or  
organization

competitor analysis  
analysis, decomposition and comparison of products or services that are perceived as similar to, or as having some similar characteristics to, the object of a design study; used to functional requirements, performance standards and other benchmarks.

behavior  
or role

immersion  
here, a technique for examining situated activities and/or gathering user, functional, or system requirements through complete immersion within the situation in question; may involve role-playing, but is more often limited to actual experience.

expert interviews  
interviews with individuals w/ very familiar with the project: content domain or are expert of tool being developed.

activity

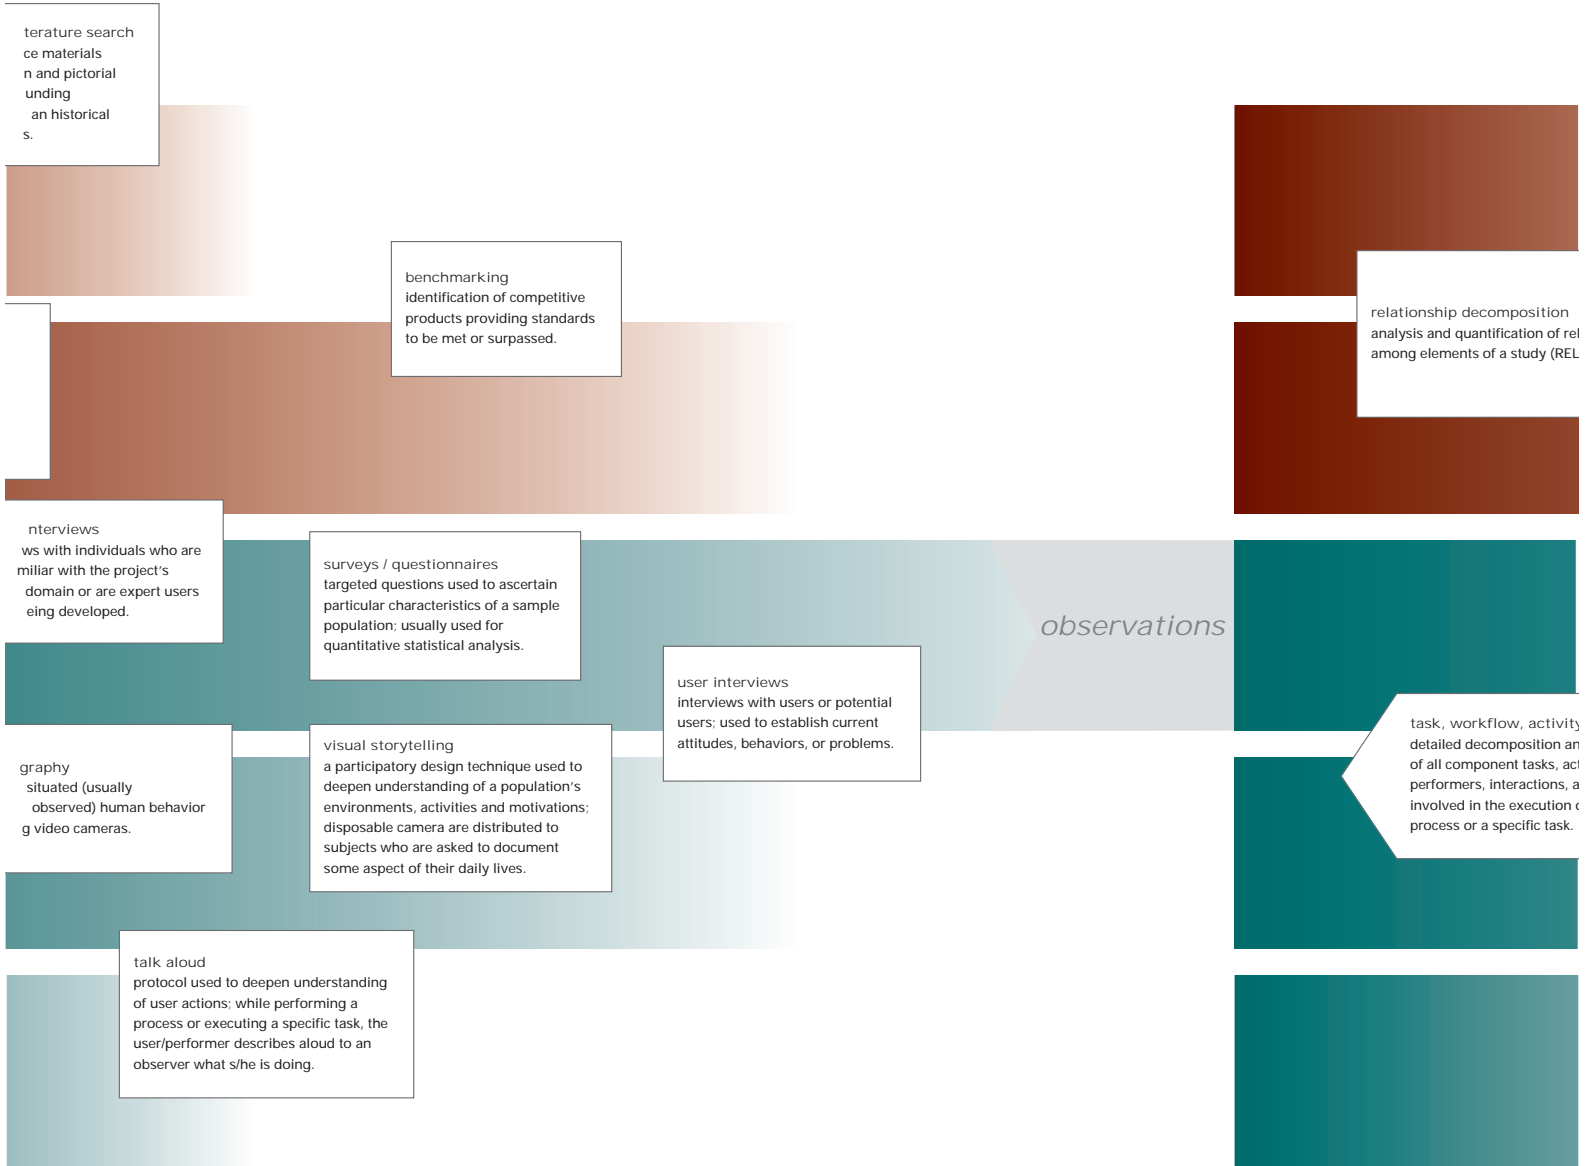

video ethnography  
description of situated (usually naturalistically observed) human behavior captured using video cameras.

action

talk  
protc

examination

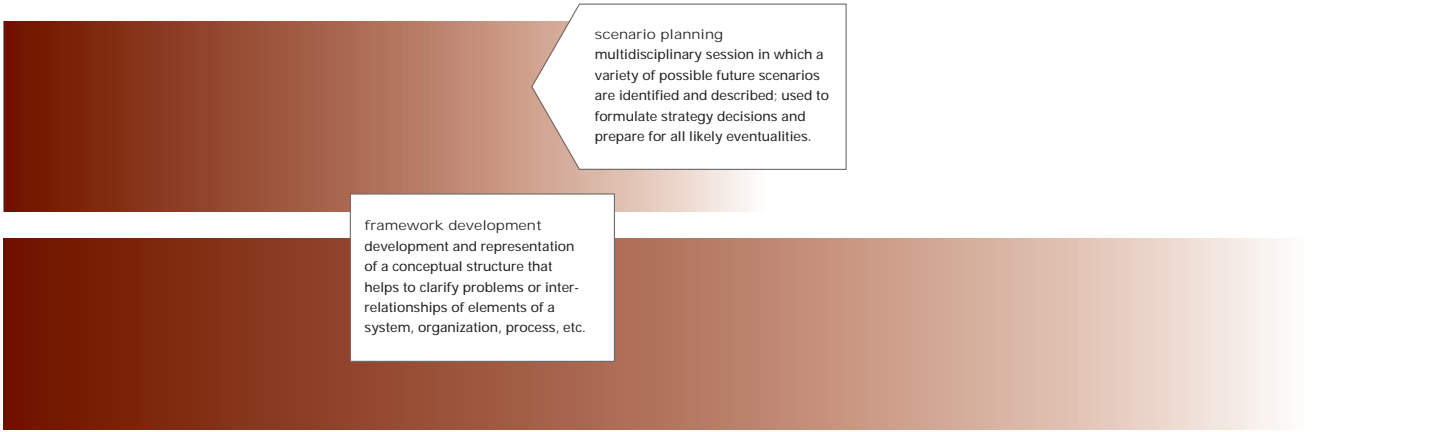

- up-front research
- both primary and secondary
- results in collection of raw data or "observations"

interpretation

- identification of trends, p
- formulation of design crit
- results in "insights," mat  
 speculations with recogn

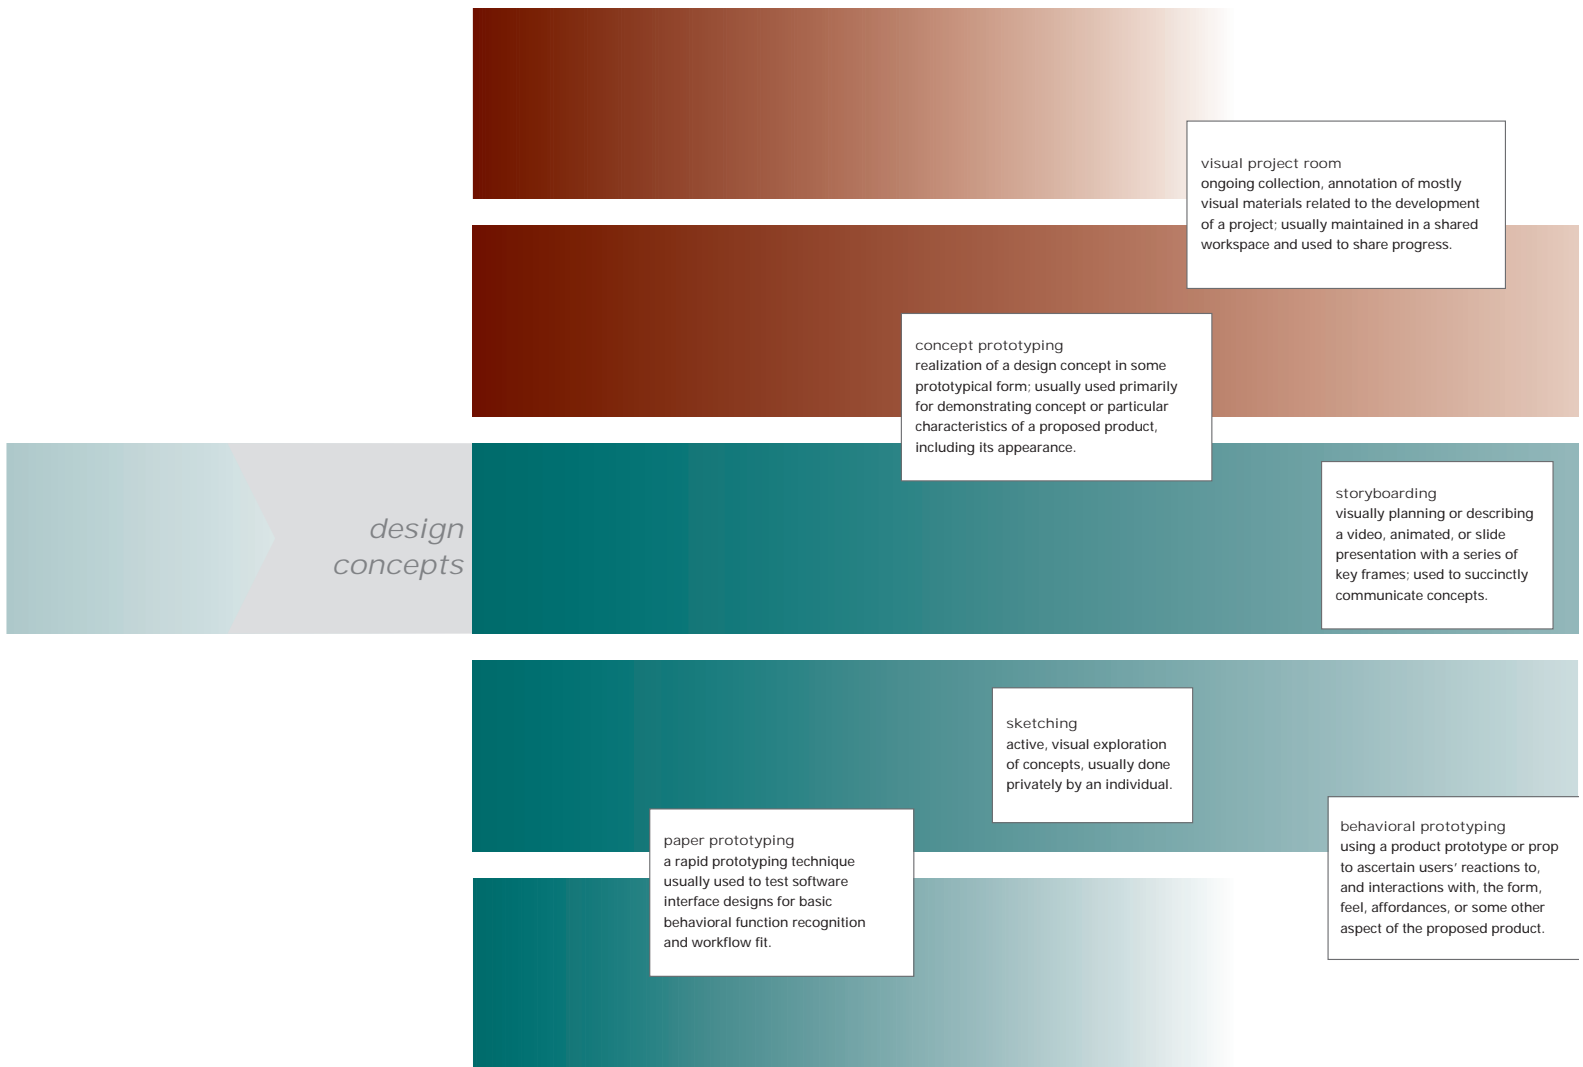

projection

- development of a new perspective, reframing or redefinition of the problem
- creation of stories exploring possibilities, opportunities
- results in "design concepts"

realization

- rapid, iterative prototype development
- creation and introduction of new realities
- results in "prototypes," the testing of which leads to new observations, new insights, and new design concepts

stly  
pment  
hared  
s.

g or describing  
d, or slide  
h a series of  
d to succinctly  
ncepts.

*prototypes*

ototyping  
prototype or prop  
rs' reactions to,  
s with, the form,  
s, or some other  
oposed product.
